(54) **Method for indicating enciphering of data transmission between a mobile communication network and a mobile station**

(57) The invention relates to a method for indicating enciphering of data transmission between a mobile communication network and a mobile station (MS) in the mobile communication network, wherein signals trans-

ferred between a mobile communication network and a mobile station are monitored, and on the basis of the signal monitored, the cipher mode is indicated to the user of the mobile station.

Description

The invention relates to a method and an apparatus for indicating enciphering of data transmission between a mobile communication network and a mobile station in the mobile communication network.

In mobile networks, at least part of the data transmission is wireless communication using radio transmitters and receivers. The radio channel is a physically open resource available to anyone by means of suitable communication equipment. This involves security risks, such as eavesdropping or disclosure of privacy of location. In digital mobile networks, such as GSM networks, digital data transmission is used which is difficult to eavesdrop. Further, it is possible to use identification of the caller and enciphering in data transmission. For preventing eavesdropping in digital mobile networks, enciphering methods have been developed for enciphering the speech and data signals modified in digital form. Moreover, enciphering can be used in the transmission of other information via the radio channel, such as identification data on the mobile station (International Mobile Subscriber Identity, IMSI) and on the location (Location Area Identification, LAI). In the receiver, the enciphered signal is decoded back to deciphered speech and data. A so-called encryption key and algorithm are advantageously known to the respective sending and receiving devices only, wherein given the effective encryption algorithms presently in use, decoding a coded signal to intelligible speech and data as well as into processing signals of the bit stream by force or illegally, i.e. without the correct encryption key and algorithm, is practically impossible.

The most common digital mobile networks are cellular networks. The base station subsystem (BSS) of the mobile network comprises base transceiver stations (BTS) and base station controllers (BSC). The mobile station (MS) communicates via the radio channel with a base station close to the respective location of the mobile station. The base station communicates with the base station controller. Data transmission between the base station and the base station controller takes place usually via a cable. One base station controller controls over a group of several base stations. The base station controller, in turn, communicates with a mobile services switching centre (MSC). Several mobile services switching centres, in turn, can communicate with each other as well as with a landline communication network centre (PSTN, ISDN). The information to be transmitted is usually divided into frames containing control information, speech and data converted into digital form, and error correction information. The frame structure can have several levels, wherein frames of a higher level are formed by arranging frames of a lower level. Enciphering can be used both with control information and with speech and data. Moreover, enciphering can be realized by using different encryption keys and algorithms at different frame levels. An example of a digital data trans-

mission network is the GSM network, the standard of which contains definitions of the enciphering methods and algorithms to be used.

In the GSM network, making a mobile-originated call is conducted in a way that a GSM mobile station and the GSM system network give signals, i.e. transmit control and identification information required for making a call. In response to a request for a connection, the GSM mobile station is allotted a channel for signalling. If this is possible within the capacity of the GSM system network. On this channel, the GSM mobile station requests speech or data service from the GSM system network. On the side of the GSM system network, this request is transmitted to a mobile services switching centre (MSC), where the rights of the GSM subscriber are checked from a visitor location register (VLR).

Upon a mobile-terminated call e.g. from a subscription of a landline telephone network, the operator of the telephone network transmits e.g. the number of the receiving telephone to the mobile services switching centre. The mobile services switching centre finds out the rights of the GSM subscriber from the home location register (HLR) and from the visitor location register (VLR). After this, the GSM system network and the GSM mobile station transmit the control and identification information required for making a call.

Depending on the implementation and the configuration of the parameters, the visitor location register VLR can make a request via the mobile services switching centre to the GSM mobile station for exchange of identification information and start of enciphering. This request is made in a so-called cipher mode command message. It is, however, possible to make a call also without exchange of identification information and enciphering. In other words, the call is either enciphered or not enciphered depending on the network parameters set by the GSM system network operator.

In most common mobile communication networks currently available, however, enciphering is not optional to a user of the mobile communication network but usually an alternative function offered by the operator of the mobile network, wherein when current wireless data transmission equipment is used, the user has no certainty whether the data transmission is enciphered or not. Particularly when the mobile station is moving, the mobile station can be transferred from the area of one base station system to the area of another base station system, wherein the cipher mode of data transmission can be changed.

One purpose of the present invention is to eliminate the disadvantages described above and to provide a method for indicating enciphering of data transmission to the user of the mobile communication network. The invention is based on the idea that control signals used in data transmission between a mobile network and a mobile station are monitored and when a control signal for enciphering is detected, the cipher mode is signalled with a cipher mode indicator connected to the mobile

station. The method of the invention is characterized in that signals transferred between a mobile communication network and a mobile station are monitored, and on the basis of the signal monitored, the cipher mode is indicated to the user of the mobile station.

The apparatus according to the invention is characterized in that the apparatus comprises means for monitoring signals transferred between a mobile communication network and a mobile station, and means for indicating the cipher mode to the user of the mobile station.

The invention gives significant advantages. Using the method of the invention, the user of a data transmission device is always aware of whether the data transmission is enciphered or not. Further, by using the method of the invention, it is possible to indicate a possible change in the cipher mode during the data transmission to the user of the data transmission device.

In the following, the invention will be described in more detail with reference to the appended drawings. In the drawings,

- Fig. 1a shows the call set-up signals during a mobile-originated call in the GSM mobile communication network,
- Fig. 1b shows the call set-up signals during a mobile-terminated call in the GSM mobile communication network,
- Fig. 2 is a reduced signal chart on detection of the cipher mode by the principle of interrupting,
- Fig. 3 is a reduced signal chart on an enquiry about the cipher mode,
- Fig. 4 is a reduced signal chart on detection of the cipher mode when enquiries at regular intervals are used,
- Fig. 5 is a reduced block diagram showing the location of the most essential blocks of a cipher mode indicating device in a mobile station according to an advantageous embodiment of the invention,
- Fig. 6 is a reduced block diagram showing the implementation of a cipher mode indicating device in connection with a mobile station and a data processor,
- Fig. 7 is a reduced chart on a situation where a data transmission connection is formed between two mobile stations, and
- Fig. 8 is a reduced signal chart on an enquiry about the cipher mode in a situation where a data transmission connection is formed between

two mobile stations.

Figure 1a shows call set-up signalling during a mobile-originated call and Fig. 1b shows call set-up signals during a mobile-terminated call in the GSM mobile communication network. During call set-up signalling, enciphering information is exchanged if the cipher mode is set on. Upon call set-up signalling, the mobile communication network sends a cipher mode command message requesting the mobile station MS to start enciphering. When the mobile station MS receives this message, it sets a cipher indication data field CIND to show that the cipher mode is on. The cipher indication data field CIND used can be e.g. a predetermined binary digit. Thus the value of the binary digit can be either a logical "0" or a logical "1". For example in logical circuits having an operating voltage of 3 V, the logical "0" value corresponds advantageously to a voltage value of approximately 0V and the logical "1" value corresponds to a voltage of approximately 3 V, which is known as such. The cipher indication data field CIND used can be naturally any other data field as well, such as a byte, wherein advantageously when the value of the byte is zero, the cipher mode is off and, in a corresponding manner, when the value of the byte is different from zero, the cipher mode is on. The contents of the cipher indication data field CIND is cleared upon starting up the mobile station MS and always after a call has been ended. When the user starts a new call and the call set-up signalling advances, the value of the cipher indication data field CIND is changed in connection with the exchange of ciphering information to be different from zero, i.e. to indicate that the cipher mode is on.

Now referring to Fig. 2, when the resource control block 1 of the mobile station MS detects a cipher control signal in the communication between the mobile station and the base station, the resource control block sets the value of the cipher indication data field CIND in a cipher indicator memory block 2 to correspond with the cipher indication data. The cipher indicator memory block 2 reads the value of the cipher indication data field and detects that a new value has been set in it, wherein the cipher indicator memory block 2 makes a request for interruption. A user interface block 3 detects the request for interruption, wherein it sends an enquiry on the cipher mode to the cipher indicator memory block 2 which returns the data on the cipher mode to the user interface block 3. Following this, the user interface block 3 sets the cipher indicator to the mode corresponding to the ciphering data, for example with a certain sign on the display of the mobile station. The change of the cipher mode can also be indicated with an acoustic signal, wherein the user notices the change in the cipher mode also when talking to a mobile station. Thus the user does not need to have visual contact with the display of the mobile station. The user of the mobile station is informed of the cipher mode at the beginning of and during the call. This is important particularly in situations where the

cipher mode can be changed during the call, for example when the mobile station is moving.

Figure 3 illustrates a second advantageous embodiment of the method according to the invention. Here the difference to the embodiment of Fig. 2 lies primarily in that a change in the cipher indication data field does not lead to a request for interruption but the cipher indicator memory block 2 sends the cipher information to the user interface block 3 whenever the value in the cipher indicator memory block is changed. In other respects, the operation of the embodiment shown in Fig. 3 corresponds substantially to the operation of the embodiment shown in Fig. 2.

Figure 4 illustrates a third advantageous embodiment of the method according to the invention, wherein the user interface block 3 sends cipher mode enquiry messages at regular intervals to the cipher indicator memory block 2. The cipher indicator memory block 2 sends a response to the enquiry to the user interface block 3 which will transmit the cipher information to the cipher indicator. In this embodiment, a separate message on the change in the cipher indication data field is not formed. When using this embodiment, the interval of sending enquiry messages must be kept sufficiently short in order to detect a change in the cipher mode sufficiently quickly. In this embodiment, it is advantageous to form a cipher mode enquiry message at least in those situations when the mobile station moves from the area of one base station system to the area of another base station system.

During a call, it is possible to transmit so-called short message services (SMS) to the mobile station. In the transmission of short messages, the cipher mode may deviate from the cipher mode of the call in question, wherein the method of the invention can be used to indicate the cipher mode separately for the call and for the short message services. Also a change in the cipher mode can be indicated to the user both for the call and for the short message services. For indicating the cipher mode and a change in the cipher mode, signals distinguishable from each other can be used, e.g. different acoustic signals, wherein the user of the mobile station is aware of the cipher mode of both the call and the short message services.

The method according to the present invention can also be applied in a way that the existence of enciphering is indicated to the user already before starting the call. This can be implemented advantageously by providing the menu structure of the mobile station with a function whereby the user can ask the mobile communication network about the cipher mode. When this function is selected from the menu, the mobile station sends the mobile network a message inquiring the cipher mode. In practice, this can be conducted in the GSM mobile network by forcing the mobile station to a location update procedure. This procedure contains starting of enciphering if the cipher mode is active in the mobile communication network. In this way, the mobile station

can send to the mobile communication network an enquiry about the current cipher mode, which is indicated to the user e.g. by an icon in the display of the mobile station.

Problems may result in countries where enciphering is not allowed to be on during speech because of legislation or for another reason. However, enciphering can thus be on for signalling, i.e. the location update procedure shows cipher-on mode although it is not on for speech. Thus the mobile station can produce an acoustic signal when it turns on the speech channel and detects a change in the cipher mode, wherein the user will be informed that speech is not transferred in enciphered form.

Figure 5 is a reduced block diagram showing one embodiment of the apparatus according to the invention. A functional part of the central processing unit MCU consists of the resource control block 1 which processes signalling between the mobile communication network and the mobile station. The resource control block 1 is in a transmission connection via a first signal bus 4 to a data transmission bus 5. The data transmission bus 5 is connected with a memory block MEM by means of a second signal bus 6. Further, the data transmission bus 5 is connected with a user interface block UI via a third signal bus 7. The user interface block UI includes a visual display unit 8, a display unit control means 9, an acoustic signal forming element 10, and a control means 11 for the acoustic signal forming element. The display unit 8 is preferably the display of the mobile station, and the acoustic signal forming element 10 is preferably the sound generator of the mobile station, or the like.

Data transmission from the resource control block 1 to the cipher indication data field CIND is preferably controlled by the central processing unit MCU, wherein the central processing unit MCU reads the ciphering information and transmits it to the cipher indication data field CIND via the first signal bus 4, the transmission bus 5 and the second signal bus 6. Said buses can advantageously be arranged by known solutions used in connection with microcontrollers. Said signal buses can also be placed in the microcontroller itself, wherein the microcontroller comprises a central processing unit MCU, a resource control block 1, a cipher indicator memory block 2 comprising also the cipher indication data field CIND, as well as said signal buses 4, 6 and data transmission bus 5.

The central processing unit MCU has a data transmission connection also to the user interface block UI via the first signal bus 4, the data transmission bus 5 and the third signal bus 7. Consequently, the central processing unit MCU can advantageously control also the display unit control means 9 and the control means 11 for the acoustic signal forming element situated in the user interface block UI. This control can be arranged in a way that the central processing unit MCU sets the control line of the display unit control means 9 (not shown) to a logical "0" value (ca. 0V) when the cipher mode is

off. The central processing unit MCU sets the control line of the display unit control means 9 to a logical "1" value (for example ca. 3 V) when the cipher mode is on. Acoustic signal formation can be applied in a corresponding manner. Thus the central processing unit MCU sets the control line of the control means 11 for the acoustic signal forming element (not shown) to a logical "0" value, when there are no changes in the cipher mode. When the cipher mode is changed, the central processing unit MCU sets said control line for a moment to a logical "1" value and resets said control line to an "0" value after a suitable length of time. Thus the length of the acoustic signal can be influenced by the duration of the "1" value state.

Data transmission between different blocks in the apparatus according to the invention can be arranged using methods known as such, wherein it is unnecessary to explain it in more detail in this context.

The method of the present invention can be advantageously applied also in mobile stations currently in use in a way that the functions required in the method are provided in the operational software of the mobile station. Thus no changes will be required in the hardware of the mobile station.

The invention can also be applied in a way that part of the functions required in the method are provided in the operational software of the mobile station and part of them are provided in the software of a data processor which is in transmission connection with the mobile station. One such embodiment is illustrated as a reduced block diagram in Fig. 6.

In this embodiment, the mobile station is also used as a so-called wireless modem in connection with a data processor, such as a personal computer, wherein a data transmission connection is formed from the data processor PC via the mobile communication network e.g. to another data processor. In this case, it is advantageous to indicate the cipher mode as a certain sign on the display 12 of the data processor and possibly also as an acoustic signal by the acoustic signal forming element 13 of the data processor. The cipher indicator memory block 2 transmits information on a change in the cipher indication data field advantageously to the data processor PC by means of a mobile station connection element 14 and a PC connection bus 15. The data processor PC is provided with application software which controls that the data on the change in the cipher indication data field is read in the data processor PC from a data processor connection element 16 and processed preferably in the central processing unit 17 of the data processor. After this the data processor PC sends out a cipher mode enquiry message which is transmitted back to the cipher indicator memory block by means of the data processor connection element 16, the PC connection bus 15 and the mobile station connection element 14. In response to the enquiry message, the cipher indicator memory block 2 sends the cipher data to the data processor PC. From the data processor PC, the cipher data is read

from the data processor connection element 16 and transmitted to the cipher mode indicator. The cipher mode indicator is preferably the display unit 12 and possibly also the acoustic signal forming element 13 of the data processor. Thus the cipher mode is indicated by a suitable symbol on the display unit 12 of the data processor. In a corresponding way, a change in the cipher mode is indicated e.g. as an acoustic signal by the acoustic signal forming element 13 of the data processor. Also the operation and structure of the data processor PC are generally known and need not be explained in more detail in this context.

Further, the invention can be applied in situations where a data transmission connection (call) is formed between two mobile stations. Thus data transmission between the first mobile station MS1 and a mobile communication network as well as between the second mobile station MS2 and a mobile communication network takes place via the radio channel. The mobile stations MS1, MS2 can be located in areas of different base stations, wherein it is possible that the cipher mode in communication between the first mobile station MS1 and the mobile network is different than in communication between the second mobile station MS2 and the mobile network. The data transmission connection between the first mobile station MS1 and the second mobile station MS2 is formed in a way known as such. After the connection has been made, it is possible e.g. for the first mobile station MS1 to enquire the cipher mode of the second mobile station MS2 (Fig. 8). The enquiry can be made for example as call control signalling, such as in the GSM mobile network, and also if the ISDN between the mobile services switching centres MSC is in the user-user information element according to the GSM Standard 04.08. The resources control block 1 of the first mobile station MS1 forms a cipher mode enquiry message and transmits it to the second mobile station. The resource control block 18 of the second mobile station detects the cipher mode of the second mobile station and forms a response message where the cipher mode is transmitted to the resource control block 1 of the first mobile station. After this, the resource control block 1 of the first mobile station MS1 sets the cipher indication data field as disclosed above in this description. The first mobile station MS1 can also be provided with a second cipher indication data field for recording cipher data between the second mobile station MS2 and the mobile communication network. Thus the user of the mobile station MS1, MS2 can be given the cipher mode separately for communication between the first mobile station MS1 and the mobile network and for communication between the second mobile station MS2 and the mobile network. In another alternative, the user of the mobile station MS1, MS2 is given the cipher mode so that if communication between both mobile stations MS1, MS2 and the mobile network is enciphered, the user of the mobile station MS1, MS2 is informed that the cipher mode is on. In a different case the user is in-

formed that the cipher mode is off.

If the cipher mode in the second mobile station MS2 is changed during a call, it sends a message on the change in the cipher mode by user-user signalling.

For enquiring the cipher mode of communication [to and from] the second mobile station MS2, also other methods can be used, such as short message services (SMS).

The ISDN telecommunication network (Integrated Services Digital Network) provides also an optional user-to-user signalling service (UUS) which makes communication possible between telecommunication terminals in a data transmission connection with each other. Thus, if a data transmission connection is made from a mobile station MS to a telecommunication terminal of the ISDN type, the mobile station MS can send the telecommunication terminal an enquiry about the cipher mode by using the user-to-user signalling service. If the telecommunication terminal does not recognize the enquiry message of the mobile station MS, the mobile station MS will not receive a response to the enquiry, or the response will consist of an unidentified command or another corresponding message. In such a case, the mobile station MS can deduce that the telecommunication terminal is not a mobile station but most probably a telecommunication terminal connected with a landline telecommunication network. In this situation, the display unit of the mobile station MS indicates the user of the mobile station for example that the cipher mode between the second telecommunication terminal and the telecommunication network is unknown.

For indicating the cipher mode and a change in the cipher mode to the user of the mobile station MS, also other methods, known as such, can be used. For example, the cipher mode can be indicated by a light source, such as a light-emitting diode (LED). Consequently, for example when the cipher mode is on, a control voltage is supplied to the LED (the LED is emitting) and when the communication is not enciphered, no control voltage is supplied to the LED (the LED is unlit). A change in the cipher mode can be advantageously indicated by flashing the LED. Thus for example when the communication is not enciphered, the LED is unlit, and when the communication becomes enciphered, the LED flashes for a moment after which the LED will emit light continuously as long as the cipher mode is on. In a corresponding manner, when the communication becomes unenciphered, the LED will flash for a moment before it is turned off.

Further, so-called vibration batteries have been developed for mobile stations whereby the mobile station can be made to vibrate in a muffled way. Thus the cipher mode of data transmission can be indicated also by a vibration battery, wherein for example upon a change in the cipher mode, a control signal is supplied to the vibration battery for a moment, which will result in vibration of the mobile station and detection of the change in the cipher mode by the user of the mobile station.

The invention is not limited only to the embodiments presented above, but it can be modified within the scope of the appended claims.

Claims

1. A method for indicating enciphering of data transmission between a mobile communication network and a mobile station (MS) in the mobile communication network, characterized in that
 - signals transferred between a mobile communication network and a mobile station are monitored, and
 - on the basis of the signal monitored, the cipher mode is indicated to the user of the mobile station.
2. A method according to claim 1, characterized in that in addition to indicating the cipher mode, a change in the cipher mode is indicated to the user of the mobile station.
3. A method according to claim 1 or 2, characterized in that the data transmission connection between the mobile communication network and the mobile station (MS) is a radio connection.
4. A method according to any of the claims 1 to 3, characterized in that the communication network is a digital communication network, such as a GSM network.
5. A method according to any of the claims 1 to 4, wherein the mobile station (MS) comprises a display unit (8) and an acoustic signal forming element (10), known as such, characterized in that the cipher mode is indicated with the display unit (8) and a change in the cipher mode is indicated with the acoustic signal forming element (10).
6. A method according to any of the claims 1 to 4, wherein the mobile station (MS) comprises a light source (LED), known as such, characterized in that the cipher mode is indicated with the light source (LED).
7. A method according to claim 6, characterized in that a change in the cipher mode is indicated with a flashing light.
8. A method according to any of the claims 1 to 4, characterized in that the cipher mode is indicated by vibration.
9. A method according to any of the preceding claims;

characterized in that the signal to be monitored is a control signal.

10. A method according to any of the preceding claims, wherein a first mobile station (MS1) and a second mobile station (MS2) are in a data transmission connection with each other through at least one mobile communication network, characterized in that the cipher mode between the mobile communication network and the first mobile station (MS1) is indicated to the user of the second mobile station (MS2). 5
11. A method according to any of the preceding claims, wherein the mobile station is used in connection with a data processor (PC) for data transmission between a mobile communication network and the data processor (PC), characterized in that the cipher mode is indicated on the display unit (12) of the data processor and a change in the cipher mode is indicated with the acoustic signal forming element (10) of the data processor. 15 20
12. An apparatus for indicating enciphering of data transmission between a mobile station (MS) and a mobile communication network in the mobile communication network, characterized in that the apparatus comprises: 25
 - means (1) for monitoring signals transferred between a mobile communication network and a mobile station (MS) and
 - means (8, 12) for indicating the cipher mode to the user of the mobile station. 30
13. An apparatus according to claim 12, characterized in that the apparatus comprises further means (10, 13) for indicating a change in the cipher mode. 35
14. An apparatus according to claim 12 or 13, characterized in that the means (8, 12) for indicating the cipher mode comprise a display unit (8) of the mobile station, and the means (10, 13) for indicating a change in the cipher mode comprise an acoustic signal forming element (10), such as a sound generator or the like. 40 45
15. An apparatus according to any of the claims 12 to 14, characterized in that the means (10, 13) for indicating a change in the cipher mode comprise a light source (LED), known as such. 50
16. An apparatus according to any of the claims 12 to 15, characterized in that the means (10, 13) for indicating a change in the cipher mode comprise means for generating vibration. 55
17. An apparatus according to any of the claims 12 to
18. An apparatus according to claim 12 or 13, characterized in that the means (8, 12) for indicating the cipher mode and the means (10, 13) for indicating a change in the cipher mode are provided in a data processor (PC) communicating with a mobile station (MS).
